
Build the chart (bootqcc())
Inputs
distribution d, q, r
parameters $\boldsymbol{\theta}$
$u,\ n,\ \alpha$
Phase I
parametric bootstrap
$M \times B$ samples
maximum likelihood fits
Control limits
[LCL, UCL]
mean over M iterations
Evaluate and use the chart
arl()
run-length simulation
in control or shifted
ARL_0, ARL_1
SD and censored runs
bootqcc_monitor()
fit each new sample
compare with limits
in / out of control
plot() of the chart
